TITLE: Steric factors of radical and molecular polymerizations of ethylene and propylene

PERIODICAL: Vysokomolekulyarnyye soyedineniya, v. 3, no. 9, 1961, 1341-1346

TEXT: The knowledge of steric factors in the reactions of chain growth, of transfer, and chain breaking in the radical or molecular mechanism is necessary since these factors determine the reactivity of polymer radicals in the initial stages at low activation energy of chain growth. The ratio between radical and molecular polymerization in the polymerization of ethylene (E) and propylene (P) is unknown. The conception of steric hindrance for low-molecular compounds and radicals which was developed by the first author (Ref. 4: Dokl. AN SSSR, 22, 127, 1953; Uspekhi khimii, 25, 263, 1956) might explain these relationships. According to this method, the steric factors of chain growth in radical and molecular polymerizations of E and P are calculated on the first links. The configurations

assumed in the calculations of activated complexes are based on the assumption that their structure is similar to that of the end products. X-ray analysis showed, for the end products, paraffin-like structure with stretched zigzag chain. The primary bimolecular compound for E is butene-1. To calculate the "rotational sums of states", the coordinates of atoms, reagents, and activated complexes were first calculated, then the product of principal moments of inertia was determined according to V. M. Gryaznov and A. V. Frost (Ref. 7: Statisticheskiye metody rascheta termodinamicheskikh velichin (Statistic methods of calculating thermodynamic values), M., 1939). The corresponding frequencies (Ref. 6: L. M. Sverdlov et al.: Optika i spektroskopiya, 5, 354, 1958) were substituted into the equation for the "vibrational sum of states". The steric factors were calculated from

$$s = \gamma \frac{kT}{hZ} \cdot \frac{Q_{A...B}}{Q_A Q_B} \exp \left[ -\frac{1}{2} + T \frac{d}{dt} \ln \left( T \frac{Q_{A...B}}{Q_A Q_B} \right) \right] \quad (1).$$

Table 2 gives the factors for molecular polymerization of E and P. In radical polymerization, the factor at the beginning of growth with CH<sub>3</sub>  
Card 4/6

B110/B101

Steric factors of radical ...

radicals is  $8.4 \cdot 10^{-5}$ , with addition of ethylene to the propyl radical  $8.4 \cdot 10^{-7}$ . On formation of amyl and hexyl radicals, the steric factor slightly decreases, and remains constant on further additions. Also for the lower factors of radical polymerization of P. ( $10^{-7}$ - $10^{-10}$ ) the steric factors considerably drop only in the initial stages. A comparison of the steric factors of both types of polymerization shows that, under the same conditions, radical polymerization must predominate over molecular polymerization, owing to the low activation energy of the former (4-6 kcal) as compared with that of the latter (38-40 kcal). The abrupt decrease of the high steric factor of dimerization on transition to the trimer explains the fact that in some unsaturated compounds (isobutylene etc.) molecular polymerization does not go beyond dimerization. The tendency of steric factors to become constant already after the first 3-4 links confirms the empirical assumption of an equal reactivity of polymer radicals of one monomer having different lengths. When estimating the reactivity of radicals, the steric factors in the reaction with monomers will have to be considered. This also applies to transfer and chain breaking reactions. There are 3 figures, 2 tables, and 10 Soviet references.

B110/B147

activated complex. Steric factors calculated from Eq. (1) and from data given in Table 1 for reactions (1)-(9) are listed in Table 2. Even the steric factor of the recombination reaction of the hydrogen atom is not 1 but of the order of 0.1. The steric factor is further lowered when the trimolecular recombination of the H atoms is taken into account. When  $\text{CH}_3$  is substituted for one hydrogen atom, an abrupt decrease of the steric factor (by two orders) occurs. A continuous decrease takes place when the size of the radical is increased ( $\text{C}_2\text{H}_5$ ,  $\text{C}_3\text{H}_7$ ). When  $\text{CH}_3$  radicals are recombined, the steric factor becomes by one order lower than in the case of similar reactions involving H and  $\text{CH}_3$ . Low steric factors of the order of  $10^{-3}$  are obtained for elementary substitution reactions of Cl and Br with  $\text{H}_2$ . Considering  $S_{T_1}/S_{T_2} = (T_2/T_1)^2$  and relating the factors in Eqs. (6) and (7) to 300°K, one finds  $3 \cdot 10^{-2}$  and  $4 \cdot 10^{-2}$ , while  $8 \cdot 10^{-3}$  and  $9 \cdot 10^{-3}$  are obtained quantum-mechanically. Radical-forming reactions between  $\text{H}_2$ ,  $\text{C}_2\text{H}_2$ , and  $\text{C}_2\text{H}_4$  and the corresponding disproportionation reactions of the radicals have steric factors ranging from  $10^{-3}$  to  $10^{-4}$ . TITLE: Steric factors and constants of the reaction rate of alkyl radical recombination

PERIODICAL: Zhurnal fizicheskoy khimii, v. 37, no. 3, 1963, 689-691

TEXT: An improved method of calculating the steric factors and constants of the recombination rate for  $H + R = HR$  and  $R + R = R_2$  is given, where  $R = CH_3, C_2H_5, C_3H_7, C_4H_9, CF_3$ . The transcendental equations  $r = r(j)$  and  $\partial \omega(r, j) / \partial j = 0$  were calculated with a ural-1 computer. The distance between two radicals in the activated complex is  $5 \text{ \AA}$  at most, the steric factor of recombination is  $10^{-2} - 10^{-7}$  according to the reacting radicals; it decreases as the radical becomes more complicated. Substitution of F for H reduces the steric factor considerably. The activation energies of recombinations are between 200 and 300 cal. The calculated constants of recombination rate are in good agreement with the experimental data, e. g. those by R. N. Snow and P. E. Peck (A. I. Chem. Card 1/2

2761. Radiation Accompanying Corrosion of Metals. Part I.  
A. A. Ulianov. *Comptes Rendus (Doklady) de l'Acad. des Sciences, U.S.S.R.* 16, 579-580, 1957. In English.—The corrosion of Al, Mg, Pb, Cd, and Zn is accompanied by the emission of radiation of wave-lengths less than 3000 Å. The intensity of this emission depends on the nature of the protective oxide film, and is proportional to the rate of corrosion. Technical applications of the phenomenon are suggested, including tests for resistance to corrosion, and of the properties of protective coverings of metals. A. J. M.

<div style="float: right; font-size: 1.2em; font-weight: bold;">B-I-10</div> <div style="clear: both;"></div> <p>           Drying and sterilizing wood and other structural materials with infra-red rays. P. H. ULJAINOV (Compt. rend. Acad. Sci. U.R.S.S., 1960, 4, 597-598).—The reflective and absorptive capacities of various building materials have been determined. The max. permeability of wood occurs at 2.7-3.0 μ. Building materials may be quickly dried by infra-red radiation from a radiator at 800°. In wood, thermal gradients of 40-80° in the outer and 20-5° per cm. in the inner layers may be achieved, with humidity gradients of 5-8% per cm. The lethal action of the rays on eggs and fungi has been studied. The fungi in wood are readily sterilized during the drying process; the thermal effect of the rays on the fungi is less marked. R. S. <p>621.313.382 : 621.3.014.3 - 82</p> <p>Simplified method of determining short circuit currents taking into account generator swing. Venikov, V. A., and Uljanov, S. A. Elektrichestvo (No. 2) 73-4 (Feb., 1946) In Russian. - When calculating short circuit currents for purposes of relay protection it is necessary to know the min. and max. currents, their distribution and phase relations. As the rotor position cannot be neglected, a general solution of the differential equation system is not possible. The alternative method due to Longley of numerical evaluation of successive integrals (Abstr. 2451 (1930)) is lengthy and difficult. A new, simple method is described which allows rapid calculation of altered phase angle and generator swing, providing the law of e.m.f. v. rotor angle is known. Derived curves show good agreement with Longley's results. A. L.</p>

**On the Cause of the "Hardness" of Electrolytic Zinc.** A. A. Butchvar and A. J. Ulianov (*Zritelnye Metally (The Non-Ferrous Metals)*, 1932, 7, 33-36; *Chem. Zentr.*, 1934, 104, 1, 2343).—The hardness of zinc does not primarily depend on the thermal treatment, since the presence of iron has a profound effect on the recrystallization process, as little as 0.2% preventing it entirely. The hardness is unaffected by 0.2% lead, but 0.1-0.2% cadmium increases it appreciably. In making zinc sheets of uniform hardness strict control of the iron content is essential.—A. R. P.

AUTHOR: Pobozhiy, G., President of the First "DOSAAF" Organization of School No 3.; Ul'kin, E., President of the Amateur Radio Club; Mamonyako, M., Council Member of the Radio Club and others.

TITLE: Indifferent Attitude towards an Important Matter. (Bezrazlichnoye otnosheniye k vashnomu delu).

PERIODICAL: Radio, 1957, Nr. 8, p 11, col 2-3 (USSR).

ABSTRACT: At the end of February an amateur radio club with 49 members was organized in KLINTSY, District of BRYANSK, affiliated to Technical School # 3.

From membership dues and with the help of the school directorate the club acquired necessary materials. The club possesses radio measuring instruments, receiving and transmitting equipment and a well equipped laboratory.

The members are divided in two groups. One group of radio amateurs elaborates and designs radio broadcasting and radio measuring installations of medium complexity, while in the other group, ultra short wave apparatus are designed and the members are trained to become wireless operators.

TITLE:

Indifferent Attitude towards an Important Matter. (Bezrazlichnoye otnosheniye k vazhnomu delu). 107-8-14/62

However, the municipal "DOBAAF" committee does not support the club.

There are grievances also against the BRYANSK Regional Radio Club. Although it had assisted in organizing the Klintsey amateur radio club, it seems to have forgotten its existence, and merely sends statements about competitions taking place. This is all its "care" for the needs of the amateur radio club.

TITLE: Adsorption properties and maximum adsorption capacity of formed synthetic type A and X zeolites

SOURCE: Zhurnal prikladnoy khimii, v. 37, no. 10, 1984, 2158-2165

TOPIC TAGS: type A zeolite, type X zeolite, adsorption, adsorption capacity

ABSTRACT: The study was made to explain the reduced adsorptive properties and reduced maximum adsorption of formed synthetic type A and X zeolites which were as much as 10-15% lower than theoretical values calculated on the basis of diluting the zeolite crystals by additives which were practically inert adsorptionwise. The lowered adsorptive properties of the formed zeolites were attributed to the lower quality of the initial zeolite crystals primarily due to incomplete washing. This was particularly noted in the CaA zeolites whose quality

Card 1/2

L 23516-65  
ACCESSION NR: AP4047120

2

was usually lower than that of the NaX zeolite crystals. The decrease in the maximum adsorption capacity of dried tablets made of thoroughly washed zeolite crystals equaled the calculated decrease due to dilution by the binding materials. The adsorptive properties of formed zeolites made from properly washed zeolite crystals and subjected to thermal treatment at 600-650C for 6-8 hours were practically unchanged. The additive content in the formed zeolite can therefore be determined from the maximum adsorption capacities for water in the initial crystalline zeolite and the formed zeolite. "In conclusion the authors thank B. A. Lipkind and Ya. V. Mnsko for supplying the zeolite samples for the investigation." Orig. art. has: 4 tables and 3 equations.
